

# Chapter 5

Slide 5-1

# Chapter 5: Algorithms

## 5.1 The Concept of an Algorithm

## 5.2 Algorithm Representation

## 5.3 Algorithm Discovery

## 5.4 Iterative Structures

## 5.5 Recursive Structures

## 5.6 Efficiency and Correctness

# Definition

- An algorithm is an **ordered set** of **unambiguous, executable** steps that defines a **terminating** process.
- **Program**
  - Formal representation of an **algorithm**
- **Process**
  - Activity of executing a program

# Ordered Set

- Steps in an algorithm must have a well-established structure in terms of the order in which its steps are executed
- May involve more than one thread (parallel algorithms)
- Steps must be an executable instruction
  - Example: Making a list of all the positive integers is not an executable instruction

# Unambiguous Steps

- During execution of an algorithm, the information in the state of the process must be sufficient to determine uniquely and completely the actions required by each step
- The execution of each step in an algorithm does not require creative skills. Rather, it requires only the ability to follow directions.

# Terminating Process

- All execution of an algorithm must lead to an end.
- Computer science seeks to distinguish problems whose answers can be obtained algorithmically and problems whose answers lie beyond the capabilities of algorithmic systems
- There are, however, many meaningful application for non-terminating processes

# Chapter 5: Algorithms

5.1 The Concept of an Algorithm

5.2 Algorithm Representation

5.3 Algorithm Discovery

5.4 Iterative Structures

5.5 Recursive Structures

5.6 Efficiency and Correctness

# Algorithm and Its Representation

- Like a story and a story book
- Example: converting temperature readings from Celsius to Fahrenheit
  - $F = (9/5)C + 32$
  - Multiply the temperature reading in Celsius by 9/5 and then add 32 to the product
  - Implemented by electronic circuit
  - Underlying algorithm is the same, only the representation differ

# Level of Details

- May cause problems in communicating algorithms
- Example:
  - “Convert the Celsius reading to its Fahrenheit equivalent” suffices among meteorologists
  - But a layperson would argue that this instruction is ambiguous
  - The problem is that the algorithm is not represented in enough detail for the layperson

# An Example: Origami

# Algorithm Representation

- Primitive
  - Set of building blocks from which algorithm representations can be constructed
- Programming language
  - Collection of primitives
  - Collection of rules stating how the primitives can be combined to represent more complex ideas

# Primitives

- Syntax
  - Symbolic representation
- Semantics
  - Concept represented (meaning of the primitive)
- Levels of abstraction

# Levels of Abstraction

- Problem
  - Motivation for algorithm
- Algorithm
  - Procedure to solve the problem
  - Often one of many possibilities
- Representation
  - Description of algorithm sufficient to communicate it to the desired audience
  - Always one of many possibilities

# Origami Primitives

# Machine Instructions as Primitives

- Algorithm based on machine instructions is suitable for machine execution
- However, expressing algorithms at this level is tedious
- Normally uses a collection of higher level primitives, each being an abstract tool constructed from the low-level primitives provided in the machine's language – formal programming language

# Pseudocode

- Less formal, more intuitive than the formal programming languages
- A notation system in which ideas can be expressed informally during the algorithm development process
- A consistent, concise notation for representing recurring semantic structure
- Comparison with flow chart

# Pseudocode Primitives

- Assignment
  - $name \leftarrow expression$
- Conditional selection
  - **if** *condition* **then** *action*
- Repeated execution
  - **while** *condition* **do** *activity*
- Procedure
  - **procedure** *name* (*generic names*)

# An Example: Greetings

**procedure** Greetings

Count  $\leftarrow$  3;

**while** (Count > 0) **do**

(print the message "Hello" and

Count  $\leftarrow$  Count - 1)

# Basic Primitives

- $\text{total} \leftarrow \text{price} + \text{tax}$
- if (sales have decreased)  
then ( lower the price by 5% )
- if (year is leap year)  
then ( divide total by 366 )  
else ( divide total by 365 )
- while(tickets remain to be sold) do  
(sell a ticket)

# Procedure Primitive

- $\text{total} \leftarrow \text{price} + \text{tax}$
- tax?
- A procedure to calculate tax

# Tax as a Procedure

## Procedure tax

```
if (item is taxable)
then (if (price > limit)
      then (return price*0.1000)
      else (return price*0.0825 )
      )
else (return 0)
```

# Nested Statements

- One statement within another

```
if (item is taxable)
  then (if (price > limit)
        then (return price*0.1000)
        else (return price*0.0825 )
      )
  else (return 0)
```

# Indentations

- Easier to tell the levels of nested statements

```
if (item is taxable)
then (if (price > limit)
      then (return price*0.1000)
      else (return price*0.0825 )
      )
else (return 0)
```

# Structured Program

- Divide the long algorithm into smaller tasks
- Write the smaller tasks as procedures
- Call the procedures when needed
- This helps the readers to understand the structure of the algorithm

```
if (customer credit is good)
then (ProcessLoan)
else (RejectApplication)
```

# The Point of Pseudocode

- To communicate the algorithm to the readers
- The algorithm will later turn into program
- Also help the program maintainer or developer to understand the program

# Chapter 5: Algorithms

5.1 The Concept of an Algorithm

5.2 Algorithm Representation

5.3 Algorithm Discovery

5.4 Iterative Structures

5.5 Recursive Structures

5.6 Efficiency and Correctness

# Algorithm Discovery

- Development of a program consists of
  - Discovering the underlying algorithm
  - Representing the algorithm as a program
- Algorithm discovery is usually the more challenging step in the software development process
- Requires finding a method of solving the problem

# Problem Solving Steps

1. Understand the problem
2. Get an idea
3. Formulate the algorithm and represent it as a program
4. Evaluate the program
  1. For accuracy
  2. For its potential as a tool for solving other problems

# Not Yet Sure What to Do

1. Understand the problem
2. Get an idea
3. Formulate the algorithm and represent it as a program
4. Evaluate the program
  1. For accuracy
  2. For its potential as a tool for solving other problems

# Difficulties

- Understanding the problem
  - There are complicated problems and easy problems
  - A complete understanding of the problem before proposing any solutions is somewhat idealistic
- Get an idea
  - Take the ‘Algorithm’ course
  - Mysterious inspiration

# Solving the Problem

a. Triples whose product is 36

$$(1, 1, 36) \quad (1, 6, 6)$$

$$(1, 2, 18) \quad (2, 2, 9)$$

$$(1, 3, 12) \quad (2, 3, 6)$$

$$(1, 4, 9) \quad (3, 3, 4)$$

b. Sums of triples from part (a)

$$1 + 1 + 36 = 38$$

$$1 + 6 + 6 = 13$$

$$1 + 2 + 18 = 21$$

$$2 + 2 + 9 = 13$$

$$1 + 3 + 12 = 16$$

$$2 + 3 + 6 = 11$$

$$1 + 4 + 9 = 14$$

$$3 + 3 + 4 = 10$$

# Getting a Foot in the Door

- Work the problem backwards
  - Solve for an example and then generalize
  - Solve an easier related problem
    - Relax some of the problem constraints
- Divide and conquer
  - Stepwise refinement
    - top-down methodology
    - Popular technique because it produces modular programs
  - Solve easy pieces of the problem first
    - bottom up methodology

# Work the Problem Backwards

- Simplify the problem
- Build up a scenario for the simplified problem
- Try to solve this scenario
- Generalize the special solution to general scenarios
- Consider a more general problem
- Repeat the process

# Divide and Conquer

- Not trying to conquer an entire task at once
- First view the problem at hand in terms of several subproblems
- Approach the overall solution in terms of steps, each of which is easier to solve than the entire original problem
- Steps be decomposed into smaller steps and these smaller steps be broken into still smaller ones until the entire problem has been reduced to a collection of easily solved subproblems
- Solve from the small subproblems and gradually have it all.

# Chapter 5: Algorithms

5.1 The Concept of an Algorithm

5.2 Algorithm Representation

5.3 Algorithm Discovery

5.4 Iterative Structures

5.5 Recursive Structures

5.6 Efficiency and Correctness

# Iterative Structures

- Used in describing algorithmic process
- A collection of instructions is repeated in a looping manner

一直 repeat 到有滿意答案或是無法再改進答案

Example: 用猜測法算  $x$  的平方根

Example: 用泰勒展開式求  $\sin(x)$ ,  $\cos(x)$ , ...

# Search Problem

- Search a list for the occurrence of a particular target value
- If the value is in the list, we consider the search a success; otherwise we consider it a failure
- Assume that the list is sorted according to some rule for ordering its entries

Sequential Search vs. Binary Search

Hash ? Store and retrieve data record through hashing?

# Search Scenario

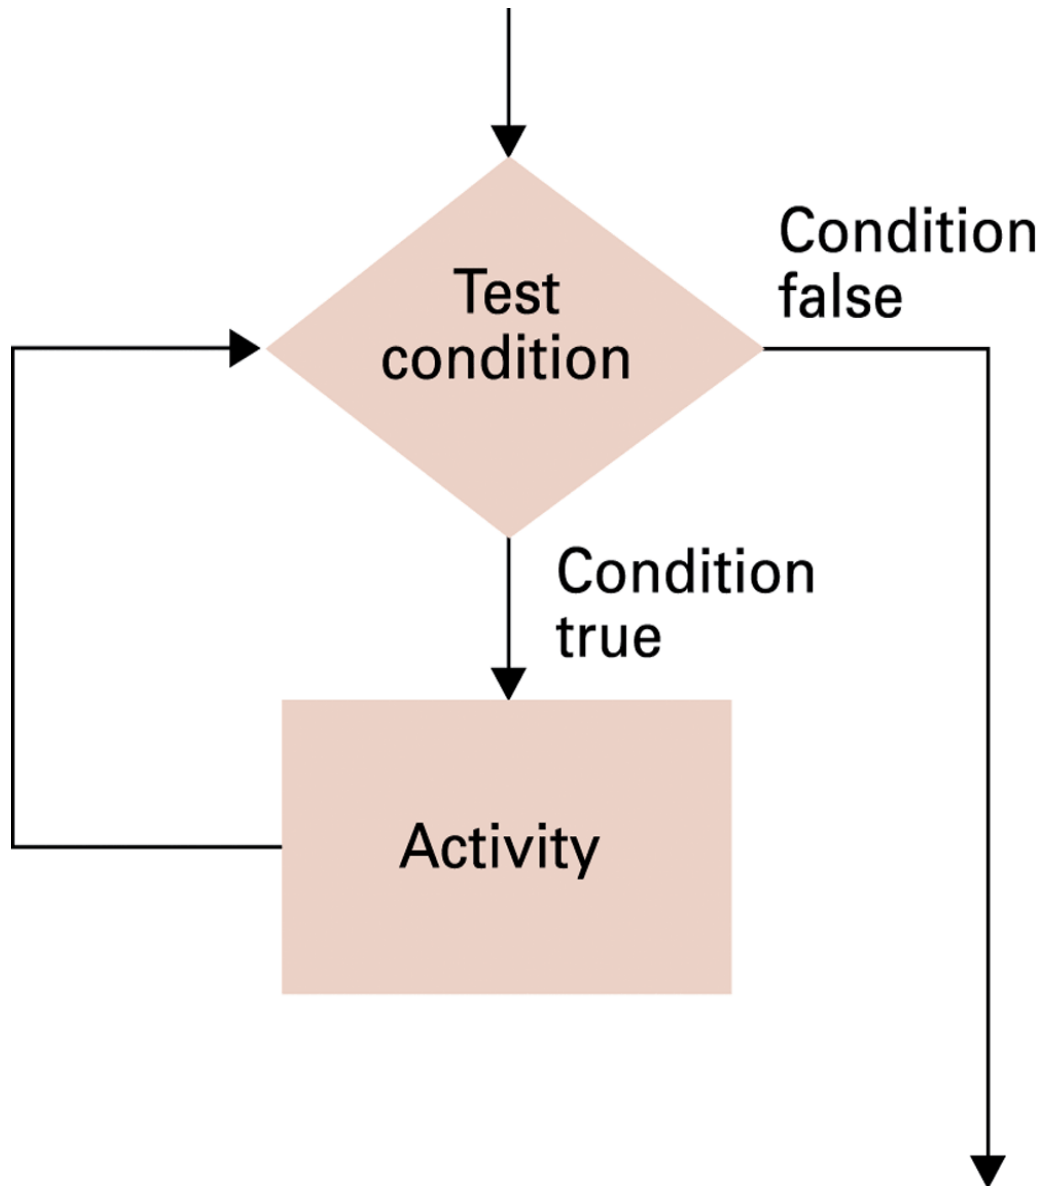

Alice  
Bob  
Carol  
David  
Elaine  
Fred  
George  
Harry  
Irene  
John  
Kelly  
Larry  
Mary  
Nancy  
Oliver

# Sequential Search Algorithm

```
procedure Search (List, TargetValue)
if (List empty)
    then
        (Declare search a failure)
    else
        (Select the first entry in List to be TestEntry;
         while (TargetValue > TestEntry and
                there remain entries to be considered)
             do (Select the next entry in List as TestEntry.);
         if (TargetValue = TestEntry)
             then (Declare search a success.)
             else (Declare search a failure.)
         ) end if
```

# The while Loop

**C/C++/Java:**

```
while(cond) {  
    /*...*/  
} // while(
```

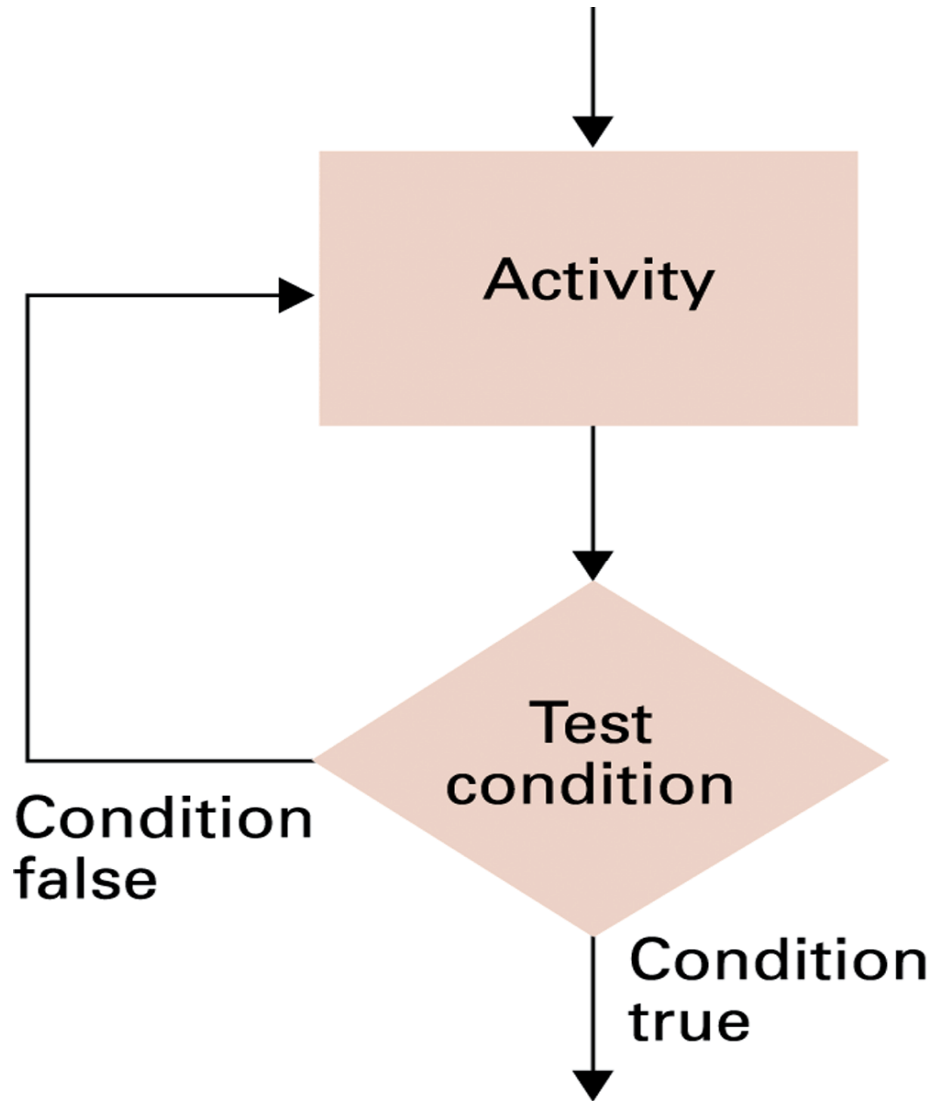

# The repeat Loop (repeat ... until)

**C/C++/Java:**

```
do {  
    /*...*/  
} while(!(cond));
```

**Pascal/Delphi:**

```
repeat  
    /*...*/  
until (cond);
```

# *while vs. repeat* Structure

- In **repeat** structure the loop's body is always performed **at least once** (posttest loop)  
(至少做一次)  
C/C++/Java: **do** { /\*...\*/ } **while**(cond.);
- While in **while** structure, the body is never executed if the termination is satisfied the first time it is tested (pretest loop) (至少做 0 次)

# Sorting 排序 (排列)

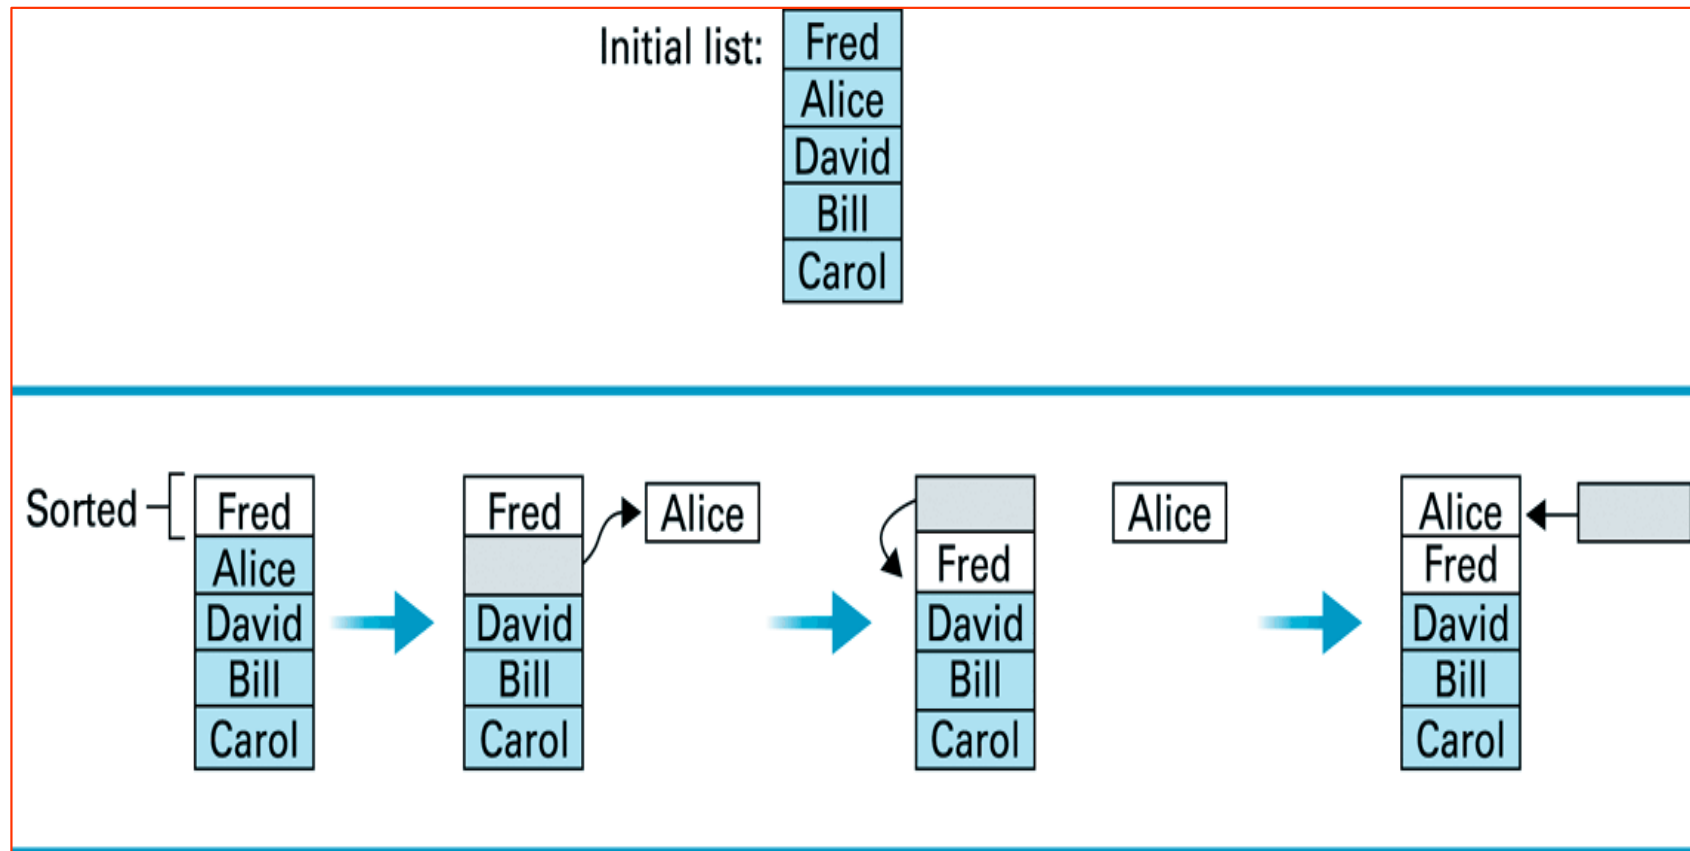

- Take a set of items, order unknown
- Return **ordered** set of the items
  - Ascending order vs. Descending order
- For instance:
  - Sorting **names** alphabetically
  - Sorting by scores in **descending** order
  - Sorting by height in **ascending** order
- ✓ Issues of interest:
  - **Running time in worst case, average/other cases**
  - Space requirements (Space complexity)

# 常見簡單 Sorting 技巧

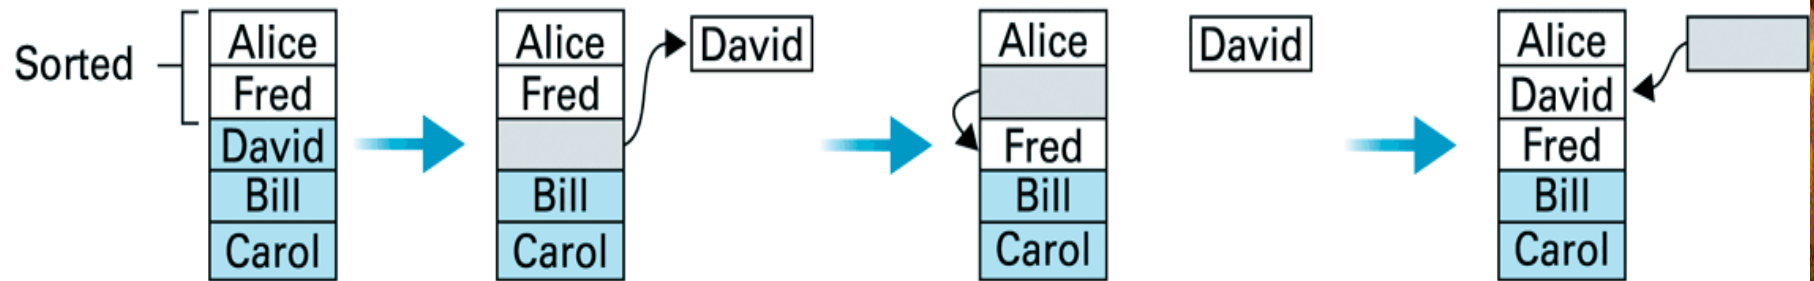

- **Insertion Sort** 插入排列法
- Selection Sort 選擇排列法
- **Bubble Sort** 氣泡排列法  
(Sibling exchange sort; 鄰近比較交換法)
- Other Sorting techniques
  - **Quick Sort, Heap Sort, Merge Sort, ..**
  - Shell Sort, Fibonacci Sort

# Sorting the list Fred, Alice, David, Bill, and Carol alphabetically (1/3)

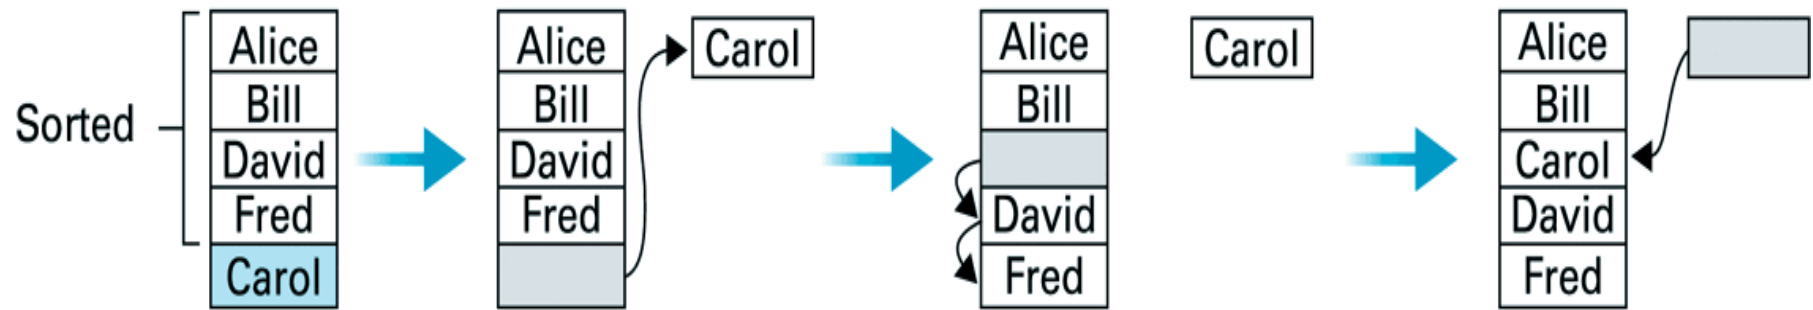

## Insertion Sort

# Sorting the list Fred, Alice, David, Bill, and Carol alphabetically (2/3)

# Sorting the list Fred, Alice, David, Bill, and Carol alphabetically (3/3)

Sorted list:

Alice
Bill
Carol
David
Fred

# The **insertion** sort algorithm expressed in pseudocode

**Key idea: Keep part of array always sorted**

**procedure** Sort (List)

$N \leftarrow 2$ ;

**while** (the value of  $N$  does not exceed the length of List) **do**

    (Select the  $N$ th entry in List as the pivot entry;

    Move the pivot entry to a temporary location leaving a hole in List;

**while** (there is a name above the hole and that name is greater than the pivot) **do**

        (move the name above the hole down into the hole leaving a hole above the name)

    Move the pivot entry into the hole in List;

$N \leftarrow N + 1$

)

# Insertion Sort in C Language

Ascending order

```
void sort( double x[ ], int nox) {  
    int n = 1, k; double tmp; /* C array 從 0 開始*/  
    while(n <= nox-1) {  
        k=n-1; tmp = x[n]; /* 我先放到 tmp */  
        while( k >= 0 && x[k] > tmp){  
            x[k+1] = x[k]; /* 前面的 copy 到下一個*/  
            --k;  
        }  
        x[k+1] = tmp;  
        ++n; /* check next element */  
    }  
}
```

Lazy evaluation  
(short-cut evaluation)

# Test the **insertion** Sort Algorithm

```
double y[ ] = {15, 38, 12, 75, 20, 66, 49, 58};
#include<stdio.h>
void pout(double*, int); void sort(double*, int);
int main( ) {
    printf("Before sort:\n"); pout(y, 8);
    sort(y, sizeof(y)/sizeof(double) );
    printf(" After sort:\n"); pout(y, 8);
}
void pout(double*p, int n) {
    int i;
    for(i=0; i<=n-1; ++i) {
        printf("%7.2f ", p[i]);
    } printf(" \n");
}
```

Before sort:

15.00 38.00 12.00 75.00 20.00 66.00 49.00 58.00

After sort:

12.00 15.00 20.00 38.00 49.00 58.00 66.00 75.00

# Insertion Sort Summary

- Best case: Already sorted  $\rightarrow O(n)$
- Worst case:
  - # of comparisons :  $O(n^2)$
  - # of exchanges:  $O(n^2)$  : 剛好相反順序時
- Space: No external storage needed
- **Stable**: keep relative order for items have same key
- In practice, good for small sets (<30 items)
- Very **efficient** on **nearly-sorted** inputs
- 想要減少 data 交換次數 : **Selection Sort**

比較的成本 vs. 交換的成本

# Selection Sort 選擇排列法

array index 由 0 到  $n-1$

Ascending order

```
void sort( double x[ ], int nox) {  
    int i, k, candt; double tmp;  
    for(i = 0; i < nox-1; ++i) {  
        candt = i; /* assume this is our candidate */  
        for( k= i+1; k<=nox-1; ++k) {  
            if(x[k] < x[candt]) candt = k;  
        }  
        tmp=x[i]; x[i]=x[candt]; x[candt]=tmp; /*第i個到定位*/  
    } // for(i  
}
```

選出剩下  
中最小的

# SelectSort(array A, length n)

array index 由 0 到 n-1

Another version of **selection** sort

```
1.  for i ← n-1 to 1    // note we are going down
2.      largest_index ← 0 // assume 0-th is largest
3.      for j ← 1 to i  // loop finds max in [1..i]
4.          if A[j] > A[largest_index]
5.              largest_index ← j
6.      next j
7.      swap(A[i], A[largest_index]) // put max in i
8.  Next i
```

選出的放最後(第 **i** 個)

# Selection Sort Summary

- Best case: Already sorted
  - Passes:  $n-1$
  - Comparisons each pass:  $(n-k)$  where  $k$  pass number
  - # of comparisons:  $(n-1)+(n-2)+\dots+1 = O(n^2)$
- Worst case:  $O(n^2)$
- Space: No external storage needed
- Very few exchanges:
  - Always  $n-1$  (better than Bubble Sort)
- Not Stable (select then swap)
  - Can be implemented as **stable** version: select then insert to correct position

# Bubble Sort-v1 氣泡排列法

array index 由 0 到 n-1

Ascending order

```
void sort( double x[ ], int nox) {  
    int i, k; double tmp;  
    for(i = nox-1; i >=1; --i) {  
        for( k= 0; k< i; ++k) {  
            if(x[k] > x[k+1]) { /* 左大右小, 需要調換 */  
                tmp= x[k]; x[k]=x[k+1]; x[k+1]=tmp;  
            }  
        } // for k  
    } // for i  
}
```

Sibling exchange sort

鄰近比較交換法

# Bubble Sort-v1 example(1/2)

15	38	12	75	20	66	49	58
15	38	12	75	20	66	49	58
15	12	38	75	20	66	49	58
15	12	38	75	20	66	49	58
15	12	38	20	75	66	49	58
15	12	38	20	66	75	49	58
15	12	38	20	66	49	75	58
15	12	38	20	66	49	58	75

第一回合 ( pass 1 ) : 7 次比較

第一回合後 75 到定位

# Bubble Sort-v1 example (2/2)

15 38 12 75 20 66 49 58 (original)

第一回合後 75 到定位:

15 12 38 20 66 49 58 | 75

第二回合後 66 到定位:

12 15 20 38 49 58 | 66 75

第三回合 ( pass 3 ) ?

12 15 20 38 49 | 58 66 75

sorted

剛剛都沒換; 還需要再做下一回合(pass)嗎 ?

# Bubble Sort-v1 Features

- Time complexity in **Worst case**: Inverse sorting

- Passes: need  $n-1$  passes
- Comparisons each pass:  $(n-k)$  where  $k$  is pass number
- Total number of comparisons:  
$$(n-1)+(n-2)+(n-3)+\dots+1 = n(n-1)/2 = n^2/2 - n/2 = O(n^2)$$

- Space: No auxiliary storage needed

- Best case: already sorted

- $O(n^2)$  Still: Many redundant passes with no swaps
- Can be improved by using a **Flag**

# Bubble Sort-v2 氣泡排列法

## 改良式氣泡排序法

array index 由 0 到 n-1

```
void sort( double x[ ], int nox) {  
    int i, k, flag; double tmp;  
    for(i = nox-1; i >=1; --i) {  
        flag = 0; /* assume no exchange in this pass */  
        for( k= 0; k< i; ++k) {  
            if(x[k] > x[k+1]) { /* 需要調換 */  
                tmp= x[k]; x[k]=x[k+1]; x[k+1]=tmp; flag=1;  
            } // if  
        } // for k  
        if(flag==0) break; /* 剛剛這回合沒交換, 不用再做 */  
    } // for i  
}
```

# Bubble Sort –v2 Features

Best case: Already sorted

- $O(n)$  – one pass

Total number of exchanges

- Best case: 0

- ***Worst*** case:  $O(n^2)$  (資料相反順序時)

➤ **Lots of exchanges:**

A problem with large **data** items

## Another version of **Bubble** sort (in pseudo code)

BubbleSort(array A[ ], int n)

array index 由 0 到 n-1

```
1. i ← n-1
2. quit ← false
3. while (i > 0 AND NOT quit) // note: going down
4.     quit ← true
5.     for j = 1 to i // loop does swaps in [1..i]
6.         if (A[j-1] > A[j]) {
7.             swap(A[j-1], A[j]) // put max in I
8.             quit ← false
9.         }
10.     next j
11. i ← i-1
12. wend
```

# Selection Sort vs. Bubble Sort

- Selection sort:
  - more comparisons than bubble sort in best case
    - Always  $O(n^2)$  comparisons :  $n(n-1)/2$
  - But fewer exchanges :  $O(n)$
  - Good for small sets/cheap comparisons, large items
- Bubble sort-v2:
  - Many exchanges :  $O(n^2)$  in worst case
  - $O(n)$  on sorted input (best case) : only one pass

# Chapter 5: Algorithms

5.1 The Concept of an Algorithm

5.2 Algorithm Representation

5.3 Algorithm Discovery

5.4 Iterative Structures

**5.5 Recursive Structures**

5.6 Efficiency and Correctness

# Recursive Structures

- Involves repeating the set of instructions as a subtask of itself
- An example is in processing incoming telephone calls using the call-waiting feature
  - An incomplete telephone conversation is set aside while another incoming call is processed
  - Two conversations are performed
  - But not in a one-after-the-other manner as in the loop structure
  - Instead one is performed within the other

# Recursion

- Execution is performed in which each stage of repetition is as a subtask of the previous stage
- Examples:
  - divide-and-conquer in **binary search**
  - **Quick sort**
  - **Hanoi tower**
  - **Factorial(n) = n \* Factorial(n-1)**
  - **GCD(m, n) = GCD(n, m%n)     if n != 0**
  - **Fibonacci series formula (Fibonacci Rabbit Problem)**

# Characteristics of Recursion

- Existence of multiple copies of itself (or multiple activations of the program)
- At any given time only one is actively progressing
- Each of the others waits for another activation to terminate before it can continue

要我算  $N!$

請你先幫我算出  $(N-1)!$

然後我就再乘上  $N$  阿就得到  $N!$  ( $N$ 階乘)

# Recursive Control

- Also involves
  - Initialization
  - Modification
  - **Test for termination (degenerative case)**
- Test for degenerative case
  - Before requesting further activations
  - If not met, assigns another activation to solve a revised problem that is closer to the termination condition
- Similar to a **loop** control

所有的 Recursive 函數  
至少要有一個 if 或類  
似的測試語句以便決  
定是否該結束！

```
if( n == 0 ) return 1; // 0 ! 是 1
```

```
if( n == 0 ) return m; // GCD(m, 0) 答案是 m
```

# qsort( ) in C Library

站在巨人肩膀上

- There is a library function for quick sort in C Language: qsort( ). (**unstable**)
- #include <stdlib.h>

```
void qsort(void *base, size_t num, size_t size,  
           int (*comp_func)(const void *, const void *))
```

void \* base --- a pointer to the array to be sorted

size\_t num --- the number of elements

size\_t size --- the element size

int (\*cf) (...) --- is a pointer to a **function** used to compare

**int comp\_func( )** 必須傳回 -1, 0, 1 代表 <, ==, >

# C++ STL <algorithm>

站在巨人肩膀上

```
#include <algorithm>
using namespace std;
int x[ ] = { 38, 49, 15, 158, 25, 58, 88, 66 }; // array of primitive data
#define n (sizeof(x)/sizeof(x[0]))
//...
sort(x, x+n); // ascending order
// what if we want to sort into descending order
sort(x, x+n, sortfun); // with compare function
sort(y, y+k, sortComparatorObject); // with Comparator Object
```

Comparison function? Default: bool operator<(first, second)

C++ Comparison function 爲bool

須傳回 true 代表 第一參數 < 第二參數 : ascending

Comparator 內要有 bool operator( ) (Obj a, Obj b) { /\*...\*/ }

<http://www.cplusplus.com/reference/algorithm/sort/>

# Java 的 `java.util.Arrays.sort()`

站在巨人肩膀上

- 可透過該物件的 `compareTo()`, 當然該 class 須 implements **`java.lang.Comparable`**
- 也可透過傳給 `sort` 一個 `Comparator`, 就是某個有 implement **`java.util.Comparator`** 之 class 的實體物件; 注意 Java 沒辦法把函數當作參數傳!!!

Java 不可以把函數當作參數!

**`java.util.Arrays.sort()`** 要傳 `Comparator` 物件?

不傳則會用要被 `sort` 之 array 的物件內的 `compareTo()`

不論是 `compareTo()`, 還是 `Comparator` 內的 `compare()` 都是類似 C 的 `qsort` 用的比較函數, `int`, 要傳回 -1, 0, 1

➤注意 C++ STL 的是須傳回 `true` 與 `false` ( see previous slide)

# Binary Search

Original list	First sublist	Second sublist
<p>Alice Bob Carol David Elaine Fred George Harry Irene John Kelly Larry Mary Nancy Oliver</p>	<p>Irene John Kelly Larry Mary Nancy Oliver</p>	<p>Irene John Kelly</p>

# Binary Search Algorithm

```
if (List empty)
  then
    (Report that the search failed.)
  else
    [Select the "middle" entry in the List to be the TestEntry;
     Execute the block of instructions below that is
     associated with the appropriate case.
     case 1: TargetValue = TestEntry
       (Report that the search succeeded.)
     case 2: TargetValue < TestEntry
       (Search the portion of List preceding TestEntry for
        TargetValue, and report the result of that search.)
     case 3: TargetValue > TestEntry
       (Search the portion of List following TestEntry for
        TargetValue, and report the result of that search.)
    ] end if
```

# Binary Search Algorithm in Pseudocode

```
procedure Search (List, TargetValue)
if (List empty)
  then
    (Report that the search failed.)

# Chapter 5: Algorithms

5.1 The Concept of an Algorithm

5.2 Algorithm Representation

5.3 Algorithm Discovery

5.4 Iterative Structures

5.5 Recursive Structures

5.6 Efficiency and Correctness

# Software Efficiency

- Measured as number of instructions executed
- notation for efficiency classes
  - $O( ? )$
  - $\Omega( ? )$
  - $\Theta( ? )$
- Best, worst, and average case

Time Complexity vs. Space Complexity

# Asymptotic Upper Bound (Big O)

- $f(n) \leq c g(n)$  for all  $n \geq n_0$
- $g(n)$  is called an **asymptotic upper bound** of  $f(n)$ .
- We write  $f(n) = O(g(n))$
- It reads  $f(n)$  equals big oh of  $g(n)$ .

# Asymptotic Lower Bound (Big Omega)

- $f(n) \geq c g(n)$  for all  $n \geq n_0$
- $g(n)$  is called an **asymptotic lower bound** of  $f(n)$ .
- We write  $f(n) = \Omega(g(n))$
- It reads  $f(n)$  equals big omega of  $g(n)$ .

# Asymptotically Tight Bound (Big Theta)

- $f(n) = O(g(n))$  and  $f(n) = \Omega(g(n))$
- $g(n)$  is called an **asymptotically tight bound** of  $f(n)$ .
- We write  $f(n) = \Theta(g(n))$
- It reads  $f(n)$  equals theta of  $g(n)$ .

# Insertion Sort in Worst Case

Comparisons made for each pivot

Initial list	1st pivot	2nd pivot	3rd pivot	4th pivot	Sorted list
Elaine David Carol Barbara Alfred	1 → Elaine David Carol Barbara Alfred	3 → David 2 → Elaine Carol Barbara Alfred	6 → Carol 5 → David 4 → Elaine Barbara Alfred	10 → Barbara 9 → Carol 8 → David 7 → Elaine Alfred	Alfred Barbara Carol David Elaine

# Worst-Case Analysis Insertion Sort

# Worst-Case Analysis Binary Search

# Big-Theta Notation

- Identification of the **shape** of the graph representing the resources required with respect to the size of the input data
  - Normally based on the worst-case analysis
  - Insertion sort:  $\Theta(n^2)$
  - Binary search:  $\Theta(\log n)$

# Formal Definition

- $\Theta(n^2)$ : complexity is  $kn^2 + o(n^2)$ 
  - $f(n)/n^2 \rightarrow k, n \rightarrow \infty$
- $o(n^2)$ : functions grow slower than  $n^2$ 
  - $f(n)/n^2 \rightarrow 0, n \rightarrow \infty$

# Problem Solving Steps

1. Understand the problem
2. Get an idea
3. Formulate the algorithm and represent it as a program
4. Evaluate the program
  1. For its potential as a tool for solving other problems
  2. For **accuracy**

Step-wise refinement is a technique for software development using a top-down, structured approach to solving a problem.

Stepwise refinement

[http://en.wikipedia.org/wiki/Program\\_refinement](http://en.wikipedia.org/wiki/Program_refinement)

# Software Verification

- Evaluate the accuracy of the solution
- This is not easy
- The programmer often does not know whether the solution is accurate (enough)
- Example: Traveler's gold chain

[http://en.wikipedia.org/wiki/Software\\_verification](http://en.wikipedia.org/wiki/Software_verification)

[http://en.wikipedia.org/wiki/Software\\_engineering](http://en.wikipedia.org/wiki/Software_engineering)

# Example: Chain Separating

- A traveler has a **gold** chain of **seven** links.
- He must stay at an isolated hotel for seven nights.
- The rent each night consists of one link from the chain.
- What is the **fewest** number of links that **must be cut** so that the traveler can pay the hotel one link of the chain each morning without paying for lodging in advance?

# Separating the chain using only three cuts

# Moral of the Story

- You thought there is no better way
- You thought it is accurate enough
- But really? who knows?

# Solving the problem with only one cut

有一大堆橘子要如何用最少種包裝？

才能應付任何要買  $1 \sim 1023$  個橘子之客戶但不用拆包？

# Ways to Level the Confidence

- For perfect confidence
  - **Prove** the correctness of a algorithm
  - Application of formal logic to prove the correctness of a program
- For high confidence
  - **Exhaustive** tests (全面測試)
  - Application specific test generation
- For some confidence
  - **Program verification** (程式驗證或證明)
  - Assertions

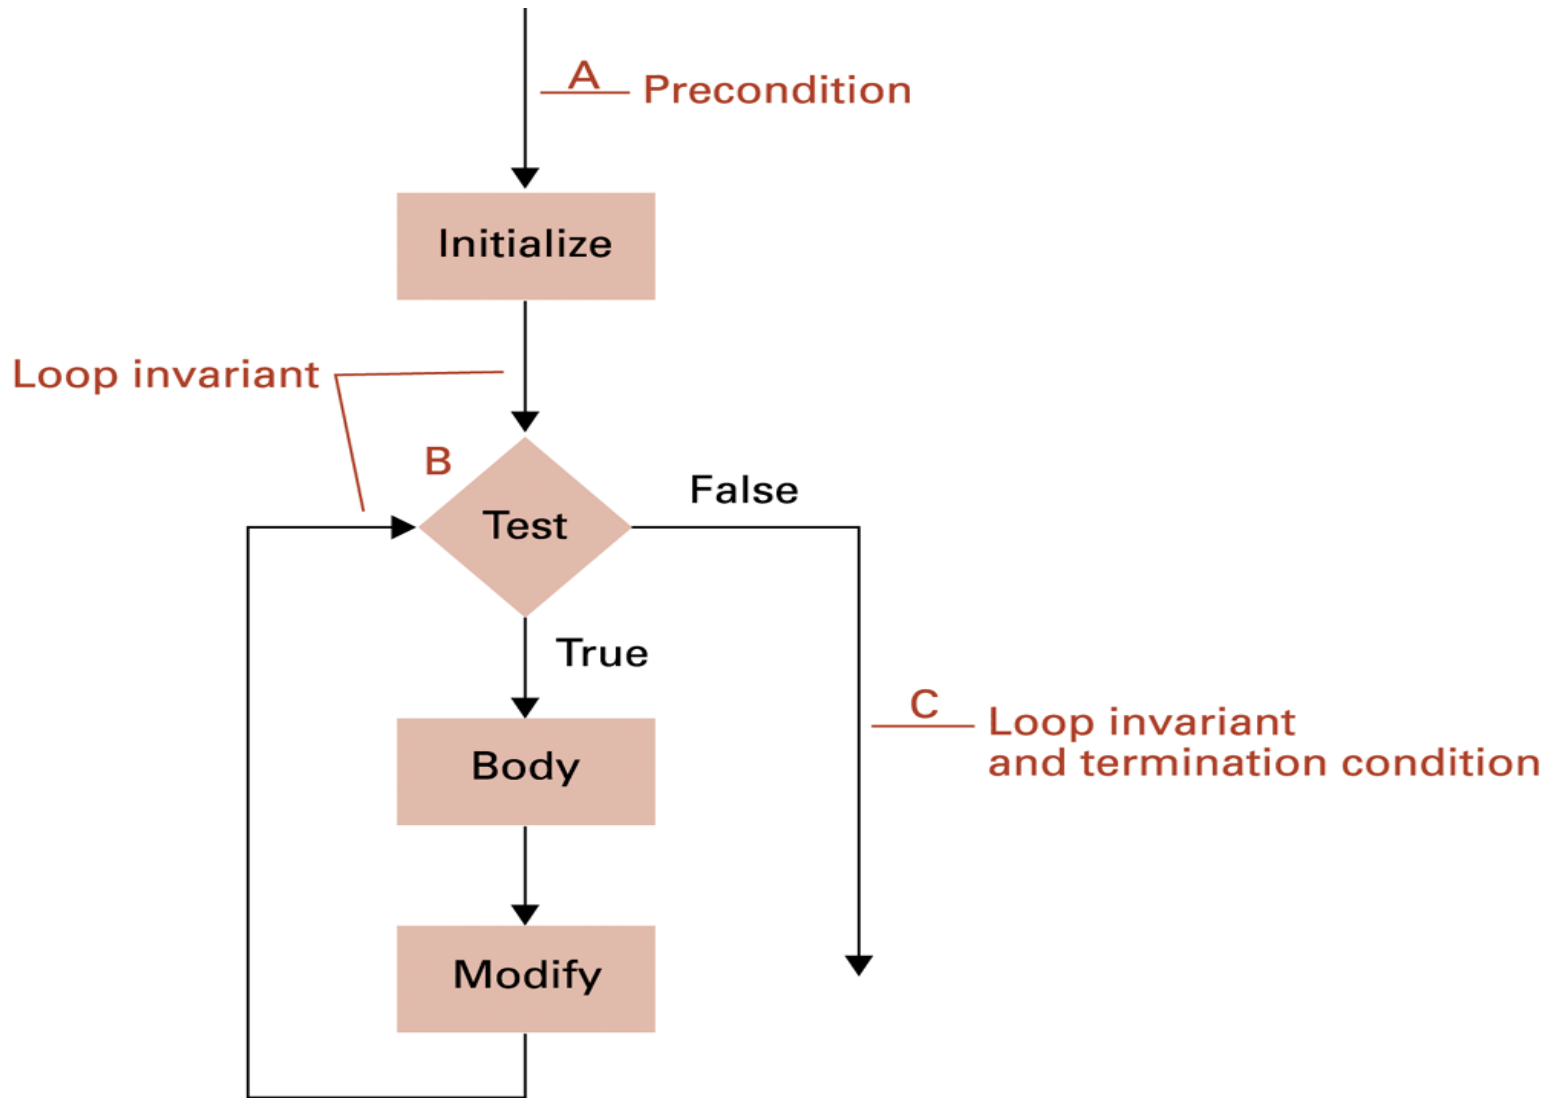

# Program Verification (1/2)

- Preconditions
  - Conditions satisfied at the beginning of the program execution
- The next step is to consider how the consequences of the preconditions propagate through the program
- Assertions
  - Statements that can be established at various points in the program

# Program Verification (2/2)

- Proof of correctness to some degree
  - Establish a collection of assertions
  - If the assertion at the end of the program corresponds to the desired output specifications, we can conclude that the program is correct

# In a *while* Structure

# Insertion Sort Algorithm

**procedure** Sort (List)

$N \leftarrow 2;$

**while** (the value of N does not exceed the length of List) **do**

    (Select the Nth entry in List as the pivot entry;

    Move the pivot entry to a temporary location leaving a hole in List;

**while** (there is a name above the hole and that name is greater than the pivot) **do**

            (move the name above the hole down into the hole leaving a hole above the name)

    Move the pivot entry into the hole in List;

$N \leftarrow N + 1$

)

# Asserting of **Insertion** Sort

- Loop invariant of the outer loop
  - Each time the test for termination is performed, the names preceding the Nth entry form a sorted list
- Termination condition
  - The value of N is greater than the length of the list
- If the loop terminates, the list is sorted

# Thank You!
